ABSTRACT

Time Savings When Working from Home*

We quantify the commute time savings associated with work from home, drawing on data for 27 countries. The average daily time savings when working from home is 72 minutes in our sample. We estimate that work from home saved about two hours per week per worker in 2021 and 2022, and that it will save about one hour per week per worker after the pandemic ends. Workers allocate 40 percent of their time savings to their jobs and about 11 percent to caregiving activities. People living with children allocate more of their time savings to caregiving.

JEL Classification: D10, J22, L23, R41
Keywords: work from home, commute times, allocation of time savings, COVID-19

All data used in this study are available at https://wfhresearch.com/gswadata/.
The COVID-19 pandemic brought a lasting shift to work from home. We quantify the savings in commute time afforded by this shift in 27 countries, drawing on our Global Survey of Working Arrangements (G-SWA). The average daily time savings when working from home is 72 minutes in our sample. To obtain this figure, we consider the commute times of persons who worked mainly from home at some point during the pandemic and compute the average of country-level means. We use regression methods to control for cross-country differences in the age, gender and education distributions, and we treat the raw U.S. mean as the baseline value.

When we account for the incidence of work from home (WFH) across people – including those who never work remotely – our data imply that WFH saved about two hours per week per worker in 2021 and 2022, and that it will save about one hour per week per worker after the pandemic ends. For a full-time worker, that amounts to 2.2 percent of a 46-hour workweek (40 paid hours plus six hours of commuting). That’s a large time savings, especially when multiplied by hundreds of millions of workers around the world.

We also provide evidence on how workers allocate these time savings. On average, those who WFH devote 40 percent of their time savings to primary and secondary jobs, 34 percent to leisure, and 11 percent to caregiving activities. These results suggest that much of the time savings flow back to employers, and that children and other caregiving recipients also benefit.

I. The Global Survey of Working Arrangements (G-SWA)

The G-SWA covers full-time workers, aged 20-59, who finished primary school in 27 countries. In addition to basic questions on demographics and labor market outcomes, the survey asks about current and planned WFH levels, commute time, and more. We design the G-SWA instrument, adapting questions from the U.S. SWAA developed by Barrero et al. (2021b). We recruit professionals to translate our original English-language questionnaire into the major languages of each country. The G-SWA went to field in 15 countries in late July and early August 2021 and in an overlapping set of 25 countries in late January and early February 2022. See Aksoy et al. (2022) for more information. As they discuss, the G-SWA samples skew to better educated persons, less so in most rich countries but very strongly so in middle-income countries.

We measure time savings when working from home as follows. In the first wave we asked: “In 2019 (before COVID) how long was your typical commute to work in minutes (one-way)?” In the second wave we ask: “How long do you usually spend commuting to and from work (in
minutes). If you are not currently commuting to work, please answer based on your commute time in 2019 (before COVID).” We obtain daily commute time by doubling the one-way commute time in the first wave and summing times to and from work in the second wave.

For those who worked mainly from home at some point during the pandemic, we obtain their allocation of time savings by asking: “During the COVID-19 pandemic, while you have been working from home, how are you now spending the time you have saved by not commuting? Please assign a percentage to each activity (the total should add up to 100%).

a) Working on your current or primary job
b) Working on a second or new secondary job
c) Childcare, home schooling, and/or caring for other relatives
d) Home improvement, chores, or shopping
e) Leisure indoors (e.g. reading, watching TV and movies)
f) Exercise or outdoor leisure”

Using the responses, we calculate the percentages of time savings devoted to jobs (a + b), leisure (e + f) and caregiving activities (c). Multiplying these percentages by total daily time savings when working from home yields the extra minutes allocated to each activity.

To obtain data on WFH days per week as of the survey week, we ask: “How many full paid days are you working from home this week?” Response options range from 0 to 5+ days per week. To obtain data on planned WFH levels, we ask: “After COVID, in 2022 and later, how often is your employer planning for you to work full days at home?” If the worker says his or her employer has neither discussed the matter nor announced a policy regarding WFH, we assign a zero value.

II. Results

Table 1 reports country-level conditional mean values for the daily savings in commute time when working from home and its allocation to other activities. To obtain these values, we fit an unweighted OLS regression of the following form to the individual-level observations:

\[ Y_{icw} = I_c + X_{icw} \beta + \varepsilon_{icw}, \]

where \( Y_{icw} \) is the outcome of interest for person \( i \) in country \( c \) and survey wave \( w \), \( I_c \) is a country-specific intercept term, \( X_{icw} \) is a vector of covariates (age groups, gender, education groups), and \( \beta \) is a coefficient vector. After fitting this regression, we recover the estimated \( \hat{I}_c \).

Using the U.S. as our reference country, we compute \( \bar{Y}_{c=US} \) as the raw U.S. mean outcome in the data pooled over
Waves 1 and 2 and obtain the adjusted country-specific intercepts as $I_c = I_c + \bar{Y}_{c=US}$. These $I_c$ values are our country-level mean outcomes, conditional on the observables in $X$.

Daily commute time savings when working from home range from 51 minutes in Serbia, 54 in Poland, and 55 in United States at the lower end to 99 minutes in India, 100 in Japan, and 102 in China at the upper end. Mean daily time savings when working from home exceed one hour in 23 of 27 countries. As remarked above, the simple average of these country-level conditional means is 72 minutes of time savings per day.

How do workers allocate these time savings, according to our survey data? On average, 40 percent goes to extra work on primary and secondary jobs. Another 34 percent goes to leisure, and 11 percent goes to caregiving activities. These results are broadly similar to the findings in Barrero et al. (2020) for the United States and in Hensher et al. (2022) for Australia. Returning to our data, extra work time on primary and secondary jobs absorbs 53 percent of the time savings in Malaysia, Singapore and Taiwan but less than 35 per cent in Germany, Greece, Japan, Italy, Poland and Spain. Respondents in Austria, Spain, and Germany allocate more than 40 per cent of their time savings to leisure. Extra caregiving activities absorb only 6 percent of time savings in Singapore and South Korea, as compared to 15 percent or more in Greece, Italy, Poland and Serbia.

Table 2 summarizes the incidence of WFH in our sample and provides information about how daily time savings vary with demographic characteristics. We consider two country-level samples, because we lack data on marital status and the presence of children in some countries. Panel A reports unconditional mean WFH levels. As of the survey week, both men and women worked about 1.7 full days at home, on average. Employer plans imply about half as many WFH days per week after the pandemic ends. Combining these results with the daily time savings in Table 1, our data say that WFH saved about two hours per week per worker in 2021 and 2022, and that it will save about one hour per week per worker after the pandemic ends. That’s equivalent to 2.2 percent of a 46-hour workweek, the sum of 40 paid hours and six hours of commuting.

Panel B shows how commute times vary in the cross section. Average daily commutes are about 10 minutes longer for highly educated workers (tertiary or graduate degree) than for those with a primary or secondary education. Perhaps the most noteworthy aspect of Panel B is how little the average daily commute times vary with demographic characteristics. In contrast, the incidence of avoided commutes due to working from home rises strongly with educational attainment (and earnings), as Barrero et al. (2021b) show for the United States.
How should we think about the value of the time savings associated with WFH? The after-tax wage rate offers a useful benchmark for the private value of commute time savings. This valuation is apt when the individual freely allocates time across activities, as in Becker (1965), and time spent commuting is neither more nor less (un)pleasant than time spent working. Later research on travel time valuations, as reviewed in Jara-Díaz (2007) and Small (2012), highlights factors that lead to departures from the benchmark. Theory and evidence suggest that the (marginal) value of commute time rises with trip duration, because longer trips are more tiresome and because the overall time constraint binds more tightly. Commuters strongly dislike unpredictable travel times, and automobile drivers strongly dislike congested road conditions. Thus, long commutes, unpredictable commute times, and congested road conditions push the private value of time savings above the after-tax wage. Conversely, short, predictable and pleasant commutes push the private value below the after-tax wage.

These observations indicate that the private benefits of the commute time savings associated with WFH are roughly 2.2 percent of after-tax earnings when the workforce demographics are similar to that of the United States and average daily commute times are around 72 minutes. The private value of the time savings will tend to be smaller in countries with shorter commutes and in countries with a smaller share of highly educated workers (because less educated workers WFH less). For example, Table 1 says the average daily commute is 55 minutes in the United States. Thus, the implied private value of the time savings associated with WFH is on the order of (55/72)(2.2) = 1.7 percent of after-tax earnings.

This figure captures only the commute time savings associated with WFH. The full private value of working from home is greater for several reasons. First, avoided commutes bring monetary savings as well as time savings. Second, workers spend less time grooming and getting ready for work when they WFH (Barrero et al., 2022). Third, working from home offers more flexibility in time use over the day and greater personal autonomy. The upshot is that the direct private value of working from home, say, two or three days a week is greater than suggested by travel time valuations applied to commute time savings. See Barrero et al. (2021b) for a deeper analysis and more evidence on what workers like (and dislike) about working from home.

Table 3 provides information on how the time savings allocated to jobs, leisure and caregiving vary with demographic characteristics and living arrangements. Each column reports a regression of daily commute time savings on the indicated covariates. All specifications
include country and wave fixed effects. The omitted group is women aged 20 to 24 with a primary or secondary education in the 27-country sample, and it is the subset who do not live with children under 14 in the 20-country sample.

Several interesting patterns emerge: First, living with children under 14 has large effects on the allocation of commute time savings. Women with children devote an extra 11.4 minutes of their daily time savings to caregiving activities, relative to the omitted group. For men, the corresponding figure is 9.0 (11.4 – 0.7 – 1.7) minutes. Second, differences between men and women in how they allocate their time savings are modest. While men devote more time savings to their jobs, the daily difference is only 2.4 minutes. Men also devote about two more minutes of their time savings to leisure. Women allocate an extra 0.7 minutes of their daily time savings to caregiving when there are no children under 14 in the household and an extra 2.4 minutes when there are. Finally, the daily time savings allocated to jobs, leisure and caregiving all rise with educational attainment. In this regard, it is helpful to recall from Table 2 that daily commute times also rise with education. These patterns are broadly consistent with U.S. evidence in Barrero et al. (2020).

III. Concluding Remarks

The pandemic-induced shift to work from home yielded large private benefits in the form of commute time savings. To gauge the magnitude of these benefits, we turn to the Global Survey of Working Arrangements and consider data on commute times and the extent of work from home in 27 countries. We estimate that work from home saved about two hours per week per worker in 2021 and 2022, and that it will save about one hour per week per worker after the pandemic ends. That amounts to 2.2 percent of a 46-hour workweek, with 40 paid hours plus six hours of commuting. As we discussed, the after-tax wage rate is a reasonable benchmark for the private value of commute time savings. Thus, we estimate that the private value of the commute time savings associated with work from home will be about 2.2 percent of after-tax earnings in the post-pandemic economy.

Work from home and the associated drop in commuting also affect individuals and society through many other channels. Kahn (2022, chapters 2 and 3) offers an extended discussion of how work from home expands personal freedom, improves life quality, brings new employment opportunities, and builds social capital in residential communities. More work from
home also means lighter loads on transport systems and, in particular, less congestion at peak travel times. The available evidence, as reviewed in Hook et al. (2020), suggests that work from home reduces economy-wide energy consumption and pollution. Barrero et al. (2021a) consider how the ability to work remotely improves economic and social resilience during pandemics and other disasters that inhibit travel and in-person work. Aksoy et al. (2022) and Glaeser (2022) consider the challenges for cities presented by the big shift to work from home. Vielkind (2023) highlights the particular challenges presented by the large drop in public transit ridership.

**Notes:** Panel A reports unconditional means of WFH days per week in our sample. The first row shows the average WFH days in the survey week, based on 33,091 G-SWA respondents. The second row shows the average value of employer plans for WFH days per week after the pandemic ends, based on 34,875 G-SWA respondents. Panel B reports unconditional means of daily commute times among those who worked mainly from home at some point during the COVID-19 pandemic, based on 19,027 G-SWA respondents. The education category refers to the highest level attained. We weight each individual-level observation equally in computing the means in this table. Weighting each country equally yields similar results.
