The Institute for the Study of Labor (IZA) in Bonn is a local and virtual international research center and a place of communication between science, politics and business. IZA is an independent nonprofit company supported by Deutsche Post World Net. The center is associated with the University of Bonn and offers a stimulating research environment through its research networks, research support, and visitors and doctoral programs. IZA engages in (i) original and internationally competitive research in all fields of labor economics, (ii) development of policy concepts, and (iii) dissemination of research results and concepts to the interested public.

IZA Discussion Papers often represent preliminary work and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be available directly from the author.

ABSTRACT

Economic Surplus and Derived Demand^{*}

Most demand – especially labor demand – is derived from the demand for some other product. This note demonstrates that the usual analysis of economic rent, as typically explained for the case of consumers' surplus, carries over to the case of derived demand.

JEL Classification: D00, D61

Keywords: derived demand, indirect demand, consumers' surplus, economic rent

^{*} I thank Robert Schlicht for a simplifying suggestion.

Economic Surplus and Derived Demand

1 Introduction

ALFRED MARSHALL (1920, v.vi.4) has pointed out that most demand – especially labor demand – is derived from the demand for some other product. He wrote: “To take another illustration, the direct demand for houses gives rise to a joint demand for the labour of all the various building trades, and for bricks, stone, wood, etc. which are factors of production of building work of all kinds, or as we may say for shortness, of new houses. The demand for any one of these, as for instance the labour of plasterers, is only an indirect or derived demand.”

This note demonstrates that the usual analysis of economic rent, as typically explained for the case of consumers’ surplus, carries over to the case of derived demand. The assertion comes as no surprise; rather such is typically presupposed in all kinds of cost-benefit considerations involving derived demand, yet there is, to the best of my knowledge, no demonstration to be found in the textbooks or the literature. This note is intended to fill the gap.

2 Derived Demand

Consider a market for a consumer good with the falling demand curve (inverse demand function)

$$p = p(x) , p' < 0 \tag{1}$$

where x denotes the quantity demanded at price p .

Assume that the commodity is produced by many firms by means of some input n (labor, for instance) according to a production function

$$x_i = f_i(n_i) , f_i' > 0 , f_i'' < 0 .$$

where the index i refers to firm number i .¹

Profits of firm i are $p_i f_i(n_i) - w n_i$, and the profit maximizing level of production is characterized by the marginal productivity condition

$$p f'_i(n_i) = w. \quad (2)$$

Denote by $n = \sum_i n_i$ the aggregate labor input and define the aggregate production function f as

$$f(n) := \max \left\{ \sum_i f_i(n_i) \mid \sum_i n_i = n \right\}. \quad (3)$$

Assuming a unique interior maximum, we obtain from (2) and (3)

$$p f'(n) = w. \quad (4)$$

For any given product price p , this equation gives the ordinary (inverse) demand curve for the input (*e.g.* labor). Its slope is equal to $p f'' < 0$. The sum of profits accruing to all firms together is $\sum_i (p f_i(n_i) - w n_i)$ and hence

$$\pi = p f(n) - w n. \quad (5)$$

Any level of production x is, according to (1), uniquely related to the product price p that is necessary to clear the market. These interrelations can be incorporated within the analysis by inserting (1) and (3) into (4), yielding a relationship between factor input and input price: $p(f(n)) f'(n) = w$. This gives rise to the *indirect input demand curve*

$$w(n) := p(f(n)) f'(n). \quad (6)$$

Its slope is $w' = p f'' + p'(f')^2 < p f''$. It is, therefore, steeper than the ordinary demand curve (Figure 1).²

Consider a wage reduction from w_0 to w_1 that goes along with an employment increase from n_0 to n_1 , an output increase from x_0 to x_1 , and a price reduction from p_0 to p_1 . These quantities relate as follows:

$$\begin{aligned} x_0 &= f(n_0), & p_0 &= p(x_0) \\ x_1 &= f(n_1), & p_1 &= p(x_1). \end{aligned} \quad (7)$$

¹ In the simplest case, only one input (such as labor) is needed. For reasons of simplicity this is assumed in the following exposition. The more general case of many inputs can be covered by re-interpreting $f_i(n_i)$ as the maximum value added obtainable for firm i if factor input n_i is costlessly provided, *etc.* ² See PINDYCK and RUBINFELD (2005, 521). Note that some authors use the concept in a different sense; see VARIAN (1996, 338), for instance.

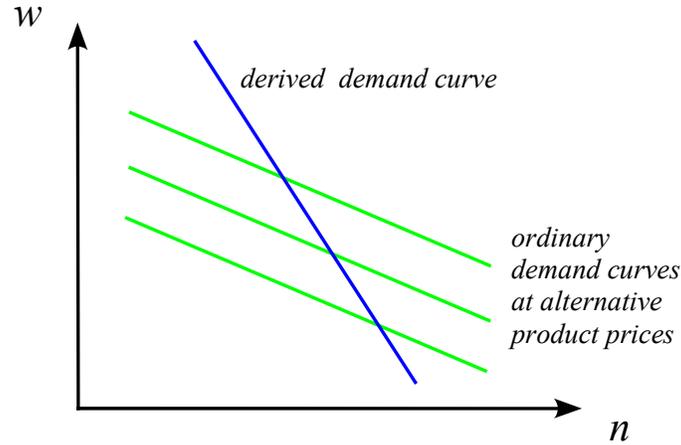

Figure 1: The derived input demand curve is steeper than the ordinary input demand curves.

Consider the area under the demand curve (1) between x_0 and output level $x = f(n)$ belonging to some employment level n :

$$P(n) = \int_{x_0}^{f(n)} p(x) dx. \quad (8)$$

Differentiation of (8) with respect to n yields

$$\frac{\partial P}{\partial n} = p(f(n)) f'(n) = w(n)$$

which implies

$$P(n_1) = \int_{n_0}^{n_1} w(n) dn.$$

This is the just the area under the derived input demand curve. Hence the corresponding areas under the product demand curve and the indirect input demand curve are identical in size (Figure 2).

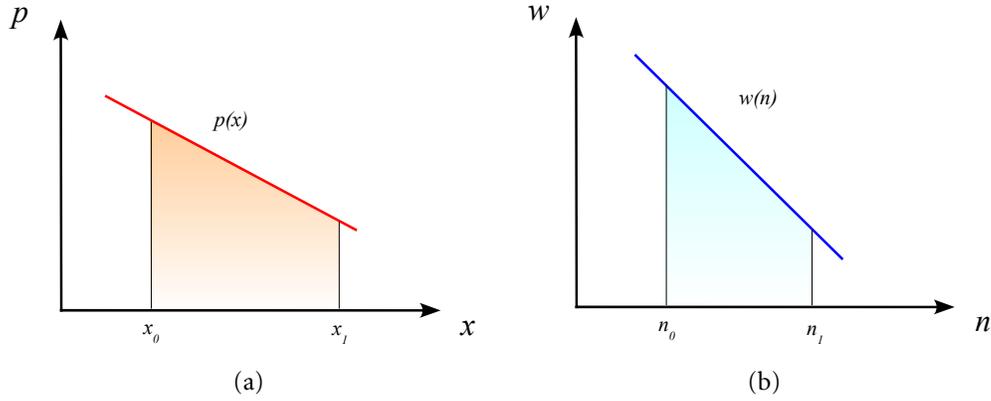

Figure 2: The area under the demand curve for output (a) and the area under the derived demand curve for input (b) between corresponding values of input and output are identical.

3 Derived Surplus

Consider now the change in consumer's surplus that results from a price change from p_0 to p_1 . It is

$$\Delta cs = p_0 x_0 - p_1 x_1 + \int_{x_0}^{x_1} p(x) dx \quad (9)$$

and is depicted in Figure 3. According to the previous argument, the integral over the demand curve equals the corresponding integral over the indirect demand curve and we have $\int_{x_0}^{x_1} p(x) dx = \int_{n_0}^{n_1} w(n) dn$. The profits associated with the different levels of production are

$$\begin{aligned} \pi_0 &= p_0 x_0 - w_0 n_0 \\ \pi_1 &= p_1 x_1 - w_1 n_1 \end{aligned}$$

and the change in profits is

$$\Delta \pi = \pi_1 - \pi_0.$$

Hence (9) can be written as

$$\Delta cs + \Delta \pi = w_0 n_0 - w_1 n_1 + \int_{n_0}^{n_1} w(n) dn. \quad (10)$$

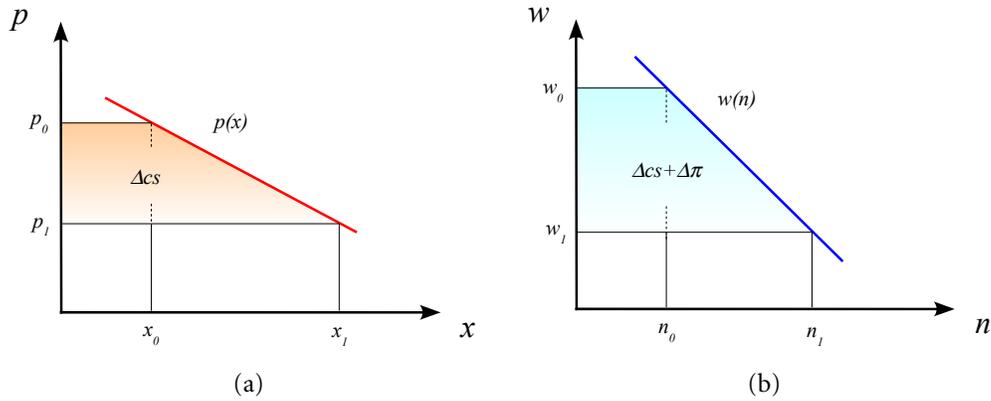

Figure 3: The change in consumers' surplus Δcs is given by the shaded area left of the final demand curve (a). The analogous area left of the derived demand curve (b) gives the change in economic rent as the sum of the changes in consumers' surplus Δcs and profits $\Delta \pi$.

The left-hand side gives the change in economic rent as the sum of the changes in consumers' surplus Δcs and profits $\Delta \pi$. The right-hand side gives the surplus area in the derived demand diagram, which is, thus, a measure for the increase in economic rent induced by a price decrease of input from w_0 to w_1 and an entailed price decrease of the final product from p_0 to p_1 . (Figure 3).
